## **INTRODUCTION TO A-LEVEL MATHS AT GCH**

Thank you for choosing to study mathematics at The Grey Coat Hospital. The Mathematics Department is committed to ensuring that you make good progress throughout your A-level course. To ensure that you have the strongest possible start in September, we have prepared this workbook and recommend that you work through it during your summer holidays. You should have covered all of these topics during your studies at GCSE and they are treated as assumed knowledge at A-Level (this means we assume you have a good understanding of them and will quickly build on and deepen this understanding).

Please ensure that you are regularly dedicating time over the holidays to complete this workbook and that you don't just leave it until the last few days. Three months is a long time to go without any mathematics and you will quickly notice that things you were able to do easily during your GCSEs (like factorising when  $a > 1$  or using the cosine rule) are a significantly more challenging after an extended break.

By the first lesson in September, you will need to have completed the entire workbook. This will involve keeping all of your work organised in either an exercise book or a folder, completing all of the "Practice" questions (and ideally some of the "Extend" questions) and marking all of your work with a green pen using the answers at the end of each section.

In the second week of term, you will take a test focusing on the content of this workbook to determine your strengths, weaknesses and suitability for the course. If it is clear that there are large gaps in your pre-requisite GCSE knowledge then you will be required to attend Maths Clinic and sit an additional test at a later date. We have included a practice test (and answers) at the end of this workbook to help you prepare for this baseline assessment.

We hope that you will use this introduction to give you a good start to Year 12 and that it will help you to enjoy, and benefit from, the course. The more effort you put in, right from the start, the better you will do.

We have also included a reading list in case some of you find you are missing learning about Maths over the break! Enjoy!

# Expanding brackets and simplifying expressions

## A LEVEL LINKS

**Scheme of work:** 1a. Algebraic expressions – basic algebraic manipulation, indices and surds

## Key points

- When you expand one set of brackets you must multiply everything inside the bracket by what is outside.
- When you expand two linear expressions, each with two terms of the form  $ax + b$ , where  $a \neq 0$  and  $b \neq 0$ , you create four terms. Two of these can usually be simplified by collecting like terms.

## Examples

**Example 1** Expand  $4(3x - 2)$

$4(3x - 2) = 12x - 8$	<p>Multiply everything inside the bracket by the 4 outside the bracket</p>
-----------------------	--

**Example 2** Expand and simplify  $3(x + 5) - 4(2x + 3)$

$\begin{aligned} 3(x + 5) - 4(2x + 3) \\ = 3x + 15 - 8x - 12 \\ \\ = 3 - 5x \end{aligned}$	<p><b>1</b> Expand each set of brackets separately by multiplying <math>(x + 5)</math> by 3 and <math>(2x + 3)</math> by <math>-4</math></p> <p><b>2</b> Simplify by collecting like terms: <math>3x - 8x = -5x</math> and <math>15 - 12 = 3</math></p>
--	---

**Example 3** Expand and simplify  $(x + 3)(x + 2)$

$\begin{aligned} (x + 3)(x + 2) \\ = x(x + 2) + 3(x + 2) \\ = x^2 + 2x + 3x + 6 \\ = x^2 + 5x + 6 \end{aligned}$	<p><b>1</b> Expand the brackets by multiplying <math>(x + 2)</math> by <math>x</math> and <math>(x + 2)</math> by 3</p> <p><b>2</b> Simplify by collecting like terms: <math>2x + 3x = 5x</math></p>
--	--

**Example 4** Expand and simplify  $(x - 5)(2x + 3)$

$\begin{aligned} (x - 5)(2x + 3) \\ = x(2x + 3) - 5(2x + 3) \\ = 2x^2 + 3x - 10x - 15 \\ = 2x^2 - 7x - 15 \end{aligned}$	<p><b>1</b> Expand the brackets by multiplying <math>(2x + 3)</math> by <math>x</math> and <math>(2x + 3)</math> by <math>-5</math></p> <p><b>2</b> Simplify by collecting like terms: <math>3x - 10x = -7x</math></p>

# Surds and rationalising the denominator

## A LEVEL LINKS

**Scheme of work:** 1a. Algebraic expressions – basic algebraic manipulation, indices and surds

## Key points

- A surd is the square root of a number that is not a square number, for example  $\sqrt{2}$ ,  $\sqrt{3}$ ,  $\sqrt{5}$ , etc.
- Surds can be used to give the exact value for an answer.
- $\sqrt{ab} = \sqrt{a} \times \sqrt{b}$
- $\sqrt{\frac{a}{b}} = \frac{\sqrt{a}}{\sqrt{b}}$
- To rationalise the denominator means to remove the surd from the denominator of a fraction.
- To rationalise  $\frac{a}{\sqrt{b}}$  you multiply the numerator and denominator by the surd  $\sqrt{b}$
- To rationalise  $\frac{a}{b+\sqrt{c}}$  you multiply the numerator and denominator by  $b-\sqrt{c}$

# Factorising expressions

## A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

## Key points

- Factorising an expression is the opposite of expanding the brackets.
- A quadratic expression is in the form  $ax^2 + bx + c$ , where  $a \neq 0$ .
- To factorise a quadratic equation find two numbers whose sum is  $b$  and whose product is  $ac$ .
- An expression in the form  $x^2 - y^2$  is called the difference of two squares. It factorises to  $(x - y)(x + y)$ .

## Examples

**Example 1** Factorise  $15x^2y^3 + 9x^4y$

$15x^2y^3 + 9x^4y = 3x^2y(5y^2 + 3x^2)$	The highest common factor is $3x^2y$ . So take $3x^2y$ outside the brackets and then divide each term by $3x^2y$ to find the terms in the brackets
---	--

**Example 2** Factorise  $4x^2 - 25y^2$

$4x^2 - 25y^2 = (2x + 5y)(2x - 5y)$	This is the difference of two squares as the two terms can be written as $(2x)^2$ and $(5y)^2$
-------------------------------------	--

**Example 3** Factorise  $x^2 + 3x - 10$

$b = 3, ac = -10$  So $x^2 + 3x - 10 = x^2 + 5x - 2x - 10$ $= x(x + 5) - 2(x + 5)$ $= (x + 5)(x - 2)$	<ol style="list-style-type: none"> <li><b>1</b> Work out the two factors of <math>ac = -10</math> which add to give <math>b = 3</math> (5 and -2)</li> <li><b>2</b> Rewrite the <math>b</math> term (<math>3x</math>) using these two factors</li> <li><b>3</b> Factorise the first two terms and the last two terms</li> <li><b>4</b> <math>(x + 5)</math> is a factor of both terms</li> </ol>
---	--

**Example 4** Factorise  $6x^2 - 11x - 10$

<p><math>b = -11, ac = -60</math></p> <p>So</p> $6x^2 - 11x - 10 = 6x^2 - 15x + 4x - 10$ $= 3x(2x - 5) + 2(2x - 5)$ $= (2x - 5)(3x + 2)$	<ol style="list-style-type: none"> <li><b>1</b> Work out the two factors of <math>ac = -60</math> which add to give <math>b = -11</math> (-15 and 4)</li> <li><b>2</b> Rewrite the <math>b</math> term (<math>-11x</math>) using these two factors</li> <li><b>3</b> Factorise the first two terms and the last two terms</li> <li><b>4</b> <math>(2x - 5)</math> is a factor of both terms</li> </ol>
--	--

**Example 5** Simplify  $\frac{x^2 - 4x - 21}{2x^2 + 9x + 9}$

$\frac{x^2 - 4x - 21}{2x^2 + 9x + 9}$ <p>For the numerator: <math>b = -4, ac = -21</math></p> <p>So</p> $x^2 - 4x - 21 = x^2 - 7x + 3x - 21$ $= x(x - 7) + 3(x - 7)$ $= (x - 7)(x + 3)$ <p>For the denominator: <math>b = 9, ac = 18</math></p> <p>So</p> $2x^2 + 9x + 9 = 2x^2 + 6x + 3x + 9$ $= 2x(x + 3) + 3(x + 3)$ $= (x + 3)(2x + 3)$ <p>So</p> $\frac{x^2 - 4x - 21}{2x^2 + 9x + 9} = \frac{(x - 7)(x + 3)}{(x + 3)(2x + 3)}$ $= \frac{x - 7}{2x + 3}$	<ol style="list-style-type: none"> <li><b>1</b> Factorise the numerator and the denominator</li> <li><b>2</b> Work out the two factors of <math>ac = -21</math> which add to give <math>b = -4</math> (-7 and 3)</li> <li><b>3</b> Rewrite the <math>b</math> term (<math>-4x</math>) using these two factors</li> <li><b>4</b> Factorise the first two terms and the last two terms</li> <li><b>5</b> <math>(x - 7)</math> is a factor of both terms</li> <li><b>6</b> Work out the two factors of <math>ac = 18</math> which add to give <math>b = 9</math> (6 and 3)</li> <li><b>7</b> Rewrite the <math>b</math> term (<math>9x</math>) using these two factors</li> <li><b>8</b> Factorise the first two terms and the last two terms</li> <li><b>9</b> <math>(x + 3)</math> is a factor of both terms</li> <li><b>10</b> <math>(x + 3)</math> is a factor of both the numerator and denominator so cancels out as a value divided by itself is 1</li> </ol>

# Solving quadratic equations by factorisation

## Key points

- A quadratic equation is an equation in the form  $ax^2 + bx + c = 0$  where  $a \neq 0$ .
- To factorise a quadratic equation find two numbers whose sum is  $b$  and whose products is  $ac$ .
- When the product of two numbers is 0, then at least one of the numbers must be 0.
- If a quadratic can be solved it will have two solutions (these may be equal).

# Solving quadratic equations by using the formula

## A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

## Key points

- Any quadratic equation of the form  $ax^2 + bx + c = 0$  can be solved using the formula

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

# Sketching quadratic graphs

## A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

### Key points

- The graph of the quadratic function  $y = ax^2 + bx + c$ , where  $a \neq 0$ , is a curve called a parabola.
- Parabolas have a line of symmetry and a shape as shown.
- To sketch the graph of a function, find the points where the graph intersects the axes.
- To find where the curve intersects the  $y$ -axis substitute  $x = 0$  into the function.
- To find where the curve intersects the  $x$ -axis substitute  $y = 0$  into the function.
- At the turning points of a graph the gradient of the curve is 0 and any tangents to the curve at these points are horizontal.
- To find the coordinates of the maximum or minimum point (turning points) of a quadratic curve (parabola) you can use the completed square form of the function.

# Sketching cubic and reciprocal graphs

## A LEVEL LINKS

Scheme of work: 1e. Graphs – cubic, quartic and reciprocal

### Key points

- The graph of a cubic function, which can be written in the form  $y = ax^3 + bx^2 + cx + d$ , where  $a \neq 0$ , has one of the shapes shown here.

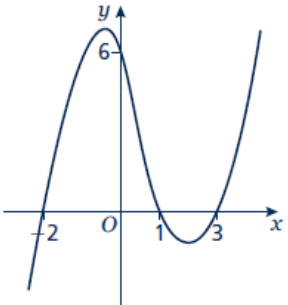

- The graph of a reciprocal function of the form  $y = \frac{a}{x}$  has one of the shapes shown here.

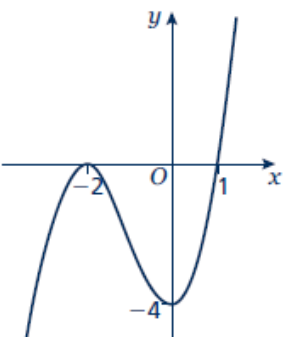

- To sketch the graph of a function, find the points where the graph intersects the axes.
- To find where the curve intersects the  $y$ -axis substitute  $x = 0$  into the function.
- To find where the curve intersects the  $x$ -axis substitute  $y = 0$  into the function.
- Where appropriate, mark and label the asymptotes on the graph.
- Asymptotes are lines (usually horizontal or vertical) which the curve gets closer to but never touches or crosses. Asymptotes usually occur with reciprocal functions. For example, the asymptotes for the graph of  $y = \frac{a}{x}$  are the two axes (the lines  $y = 0$  and  $x = 0$ ).
- At the turning points of a graph the gradient of the curve is 0 and any tangents to the curve at these points are horizontal.
- A double root is when two of the solutions are equal. For example  $(x - 3)^2(x + 2)$  has a double root at  $x = 3$ .
- When there is a double root, this is one of the turning points of a cubic function.

$$x^2 = 89$$

$$x = \sqrt{89}$$

$$x = 9.433\ 981\ 13\dots$$

## A LEVEL LINKS

Scheme of work: 2a. Straight-line graphs, parallel/perpendicular, length and area problems

### Key points

Two quantities are in direct proportion when, as one quantity increases, the other increases at the same rate.

Their ratio remains the same.

'y is directly proportional to x' is written as  $y \propto x$ .

If  $y \propto x$  then  $y = kx$ , where  $k$  is a constant.

When  $x$  is directly proportional to  $y$ , the graph is a straight line passing through the origin.

Two quantities are in inverse proportion when, as one quantity increases, the other decreases at the same rate.

'y is inversely proportional to x' is written as  $y \propto \frac{1}{x}$ .

If  $y \propto \frac{1}{x}$  then  $y = \frac{k}{x}$ , where  $k$  is a constant.

When  $x$  is inversely proportional to  $y$  the graph is the same shape as the graph of  $y = \frac{1}{x}$

# Circle theorems

## A LEVEL LINKS

Scheme of work: 2b. Circles – equation of a circle, geometric problems on a grid

### Key points

A chord is a straight line joining two points on the circumference of a circle.

So AB is a chord.

A tangent is a straight line that touches the circumference of a circle at only one point.

The angle between a tangent and the radius is  $90^\circ$ .

Two tangents on a circle that meet at a point outside the circle are equal in length.

So  $AC = BC$ .

The angle in a semicircle is a right angle.

So angle  $ABC = 90^\circ$ .

When two angles are subtended by the same arc, the angle at the centre of a circle is twice the angle at the circumference.

So angle  $AOB = 2 \times$  angle  $ACB$ .

Angles subtended by the same arc at the circumference are equal. This means that angles in the same segment are equal.  
So angle  $ACB = \text{angle } ADB$  and angle  $CAD = \text{angle } CBD$ .

A cyclic quadrilateral is a quadrilateral with all four vertices on the circumference of a circle.  
Opposite angles in a cyclic quadrilateral total  $180^\circ$ .  
So  $x + y = 180^\circ$  and  $p + q = 180^\circ$ .

The angle between a tangent and chord is equal to the angle in the alternate segment, this is known as the alternate segment theorem.  
So angle  $BAT = \text{angle } ACB$ .

## Examples

**Example 1** Work out the size of each angle marked with a letter.  
Give reasons for your answers.

Angle  $a = 360^\circ - 92^\circ$   
 $= 268^\circ$   
as the angles in a full turn total  $360^\circ$ .

Angle  $b = 268^\circ \div 2$   
 $= 134^\circ$   
as when two angles are subtended by the same arc, the angle at the centre of a circle is twice the angle at the circumference.

- 1 The angles in a full turn total  $360^\circ$ .
- 2 Angles  $a$  and  $b$  are subtended by the same arc, so angle  $b$  is half of angle  $a$ .

- The area of a trapezium =  $\frac{1}{2}h(a+b)$

### Examples

**Example 1** Estimate the area of the region between the curve  $y = (3 - x)(2 + x)$  and the  $x$ -axis from  $x = 0$  to  $x = 3$ . Use three strips of width 1 unit.

$x$	0	1	2	3
$y = (3 - x)(2 + x)$	6	6	4	0

Trapezium 1:  
 $a_1 = 6 - 0 = 6$ ,  $b_1 = 6 - 0 = 6$   
 Trapezium 2:  
 $a_2 = 6 - 0 = 6$ ,  $b_2 = 4 - 0 = 4$   
 Trapezium 3:  
 $a_3 = 4 - 0 = 4$ ,  $b_3 = 0 - 0 = 0$

- Use a table to record the value of  $y$  on the curve for each value of  $x$ .
- Work out the dimensions of each trapezium. The distances between the  $y$ -values on the curve and the  $x$ -axis give the values for  $a$ .

*(continued on next page)*

$\frac{1}{2}h(a_1 + b_1) = \frac{1}{2} \times 1(6 + 6) = 6$ $\frac{1}{2}h(a_2 + b_2) = \frac{1}{2} \times 1(6 + 4) = 5$ $\frac{1}{2}h(a_3 + b_3) = \frac{1}{2} \times 1(4 + 0) = 2$ <p>Area = 6 + 5 + 2 = 13 units<sup>2</sup></p>	<p><b>3</b> Work out the area of each trapezium. <math>h = 1</math> since the width of each trapezium is 1 unit.</p> <p><b>4</b> Work out the total area. Remember to give units with your answer.</p>
